

# ProjectOOP: Template Usage Explanation

## A Technical Deep Dive into `GameList<T>`

Documentation

December 4, 2025

### Abstract

This document provides a comprehensive explanation of how C++ templates are used in the ProjectOOP codebase, with a specific focus on the custom `GameList<T>` template class. It covers the rationale behind using templates, memory management mechanics, and comparisons with standard STL containers.

# 1 Overview

This document explains the implementation and usage of C++ templates within the project. The core focus is the `GameList<T>` class, a custom container designed to manage game objects like Obstacles, PowerUps, and Coins efficiently while providing type safety and code reusability.

## 2 What Are Templates?

### 2.1 Definition

Templates in C++ are a feature that allows you to write **generic code** that works with **any data type**. Instead of writing separate code for each type, you write one template that the compiler instantiates for each type you use.

### 2.2 Template Syntax

```
1 template <typename T>
2 class MyContainer {
3     T* data;
4     // ... methods that work with type T
5 };
```

The `typename T` is a **type parameter**—a placeholder for an actual type that will be specified when the template is used.

### 2.3 How Templates Work

When you write:

```
1 MyContainer<int> intContainer;
2 MyContainer<std::string> stringContainer;
```

The compiler generates **two separate classes** at compile time:

- One that replaces `T` with `int`.
- One that replaces `T` with `std::string`.

## 3 Why Use Templates in This Project?

### 3.1 Project Requirement

The project avoids using STL containers like `std::vector`, primarily as an academic exercise to demonstrate:

- Understanding of template mechanics.
- Manual memory management.
- Custom data structure implementation.

### 3.2 Type Safety

Without templates, alternatives would be unsafe or repetitive:

#### Option A: Type-specific classes (Code Duplication)

```
1 class ObstacleList { /* manages Obstacle* */ };
2 class PowerUpList { /* manages PowerUp* */ };
```

### Option B: Void pointers (Unsafe)

```
1 class GenericList {
2     void** data; // Loses type info! Must cast everywhere.
3 };
```

### **Option C: Templates (Chosen Solution)**

```
1 template <typename T>
2 class GameList {
3     T** data; // Type-safe and reusable
4 };
```

### 3.3 Code Reuse

With `GameList<T>`, container logic is written **once** and reused for all game object types, following the DRY (Don't Repeat Yourself) principle.

## 4 The GameList Template Class

#### 4.1 Complete Implementation

Below is the implementation found in `GameList.h`:

```
1 template <typename T>
2 class GameList {
3 public:
4     GameList() : mData(nullptr), mCapacity(0), mCount(0) {}
5
6     ~GameList() {
7         clear();
8         delete[] mData;
9     }
10
11    // Disable copy operations
12    GameList(const GameList&) = delete;
13    GameList& operator=(const GameList&) = delete;
14
15    void add(std::unique_ptr<T> item) {
16        if (mCount >= mCapacity) {
17            resize(mCapacity == 0 ? 4 : mCapacity * 2);
18        }
19        mData[mCount++] = item.release();
20    }
21
22    void updateAll(sf::Time dt, float speed) {
23        for (size_t i = 0; i < mCount; ++i) {
24            mData[i]->update(dt, speed);
25        }
26
27        // Remove items marked for deletion
28        size_t writeIdx = 0;
29        for (size_t readIdx = 0; readIdx < mCount; ++readIdx) {
30            if (!mData[readIdx]->isRemovable()) {
31                if (writeIdx != readIdx) {
32                    mData[writeIdx] = mData[readIdx];
33                }
34            }
35        }
36    }
37
38    void clear() {
39        for (size_t i = 0; i < mCount; ++i) {
40            mData[i]->~T();
41        }
42        delete[] mData;
43        mCapacity = 0;
44        mCount = 0;
45    }
46
47    void resize(size_t capacity) {
48        std::unique_ptr<T>* newData = new std::unique_ptr<T>[capacity];
49        for (size_t i = 0; i < mCount; ++i) {
50            newData[i] = std::move(mData[i]);
51        }
52        delete[] mData;
53        mData = newData;
54        mCapacity = capacity;
55    }
56
57    size_t getCount() const { return mCount; }
58
59 private:
60     std::unique_ptr<T>* mData;
61     size_t mCapacity;
62     size_t mCount;
63 }
```

```

34         writeIdx++;
35     }
36     else {
37         delete mData[readIdx];
38     }
39 }
40 mCount = writeIdx;
41 }

42 void drawAll(sf::RenderWindow& window) {
43     for (size_t i = 0; i < mCount; ++i) {
44         mData[i]->draw(window);
45     }
46 }
47 }

48 // Iterators for range-based for loops
49 T** begin() { return mData; }
50 T** end() { return mData + mCount; }

51

52 void clear() {
53     for (size_t i = 0; i < mCount; ++i) {
54         delete mData[i];
55     }
56     mCount = 0;
57 }

58 }

59
60 private:
61     void resize(size_t newCapacity) {
62         T** newData = new T*[newCapacity];
63         for (size_t i = 0; i < mCount; ++i) {
64             newData[i] = mData[i];
65         }
66         delete[] mData;
67         mData = newData;
68         mCapacity = newCapacity;
69     }

70     T** mData;           // Dynamic array of pointers to T
71     size_t mCapacity;   // Total allocated space
72     size_t mCount;      // Number of elements currently stored
73 };

```

## 4.2 Template Method Explanation

**Method:** `add()` When you call `myList.add(...)`, the `unique_ptr` is moved, ownership is released via `.release()`, and the raw pointer is stored in the internal array.

**Method:** `updateAll()` This method iterates through the array and calls `update()` on every object. It implies that type `T` **must** have an `update` method (Duck Typing).

## 5 Template Usage in Practice

### 5.1 Instantiation in TrackManager

In `TrackManager.h`, the template is instantiated three times:

```

1 class TrackManager {
2     // ...
3 private:
4     GameList<Obstacle> mObstacles;
5     GameList<PowerUp> mPowerUps;

```

```
6     GameList<Coin> mCoins;
7 }
```

This generates three distinct classes: one managing `Obstacle*`, one for `PowerUp*`, and one for `Coin*`.

## 5.2 Adding Objects

```
1 void TrackManager::spawnObstacle() {
2     auto train = std::make_unique<TrainObstacle>(* params *);
3
4     // Add to the GameList<Obstacle>
5     // 1. Ownership moved to add()
6     // 2. add() releases ownership to raw pointer inside list
7     mObstacles.add(std::move(train));
8 }
```

# 6 Memory Management

## 6.1 Ownership Transfer

The project uses a hybrid ownership model:

1. Objects are created using `std::unique_ptr` (modern C++).
2. Ownership is transferred to `GameList` via `std::move`.
3. `GameList` extracts the raw pointer and assumes responsibility for `delete`.

## 6.2 Manual Management

Since standard containers are not used, `GameList` handles memory manually:

- **Allocation:** `new T*[capacity]` allocates the array.
- **Deallocation:** The destructor calls `clear()` (to delete objects) and then `delete[] mData` (to delete the array).
